1 Introduction

SARGE, Synthetic Aperture Radar: Greenhouse Emissions: is a satellite platform designed to monitor for potential leaks of cross-Canada pipelines using synthetic aperture radar. This report details a preliminary design that should provide a solid starting point for further analysis and refinement. Assumptions and estimations are necessary at this stage of development, and their presence is clearly noted in the following sections on analysis.

Preliminary design drawings are available in the last appendix, Appendix G.

1.1 Primary Mission Objectives

The primary mission objective of SARGE is to monitor the entirety of Canada for the presence of greenhouse gasses that would indicate leaks in the transcontinental petrochemical pipelines. To this end, SARGE covers all of contiguous Canada, but does not directly cover the many islands in the far north of the territories. This should be acceptable, since there are no pipelines in those areas, and there is really only one pipeline above Hudson's Bay, ending just north of Mackenzie Bay, past Inuvik, N.W.T. [1].

1.2 Secondary Mission Objectives

Since SARGE covers the entirety of Canada (and Alaska, U.S.) any application of regular monitoring could be co-located on the satellite. Wildfire monitoring/detection, all industrial greenhouse gas emissions, and even meteorology. One of the only terrestrial applications SARGE is unsuited for is communications, as it is out of sight for about 2/3 of each day.

2 Orbit Selection

The assigned mission requirements state that this satellite is to image the entirety of Canada at least once every 14 days. To satisfy this requirement, a geosynchronous orbit with a nonstandard high inclination (121°) was chosen. The ground track of a conical SAR (shown in Figure 1) with a minimum elevation angle of 75° covers the entirety of contiguous Canada.

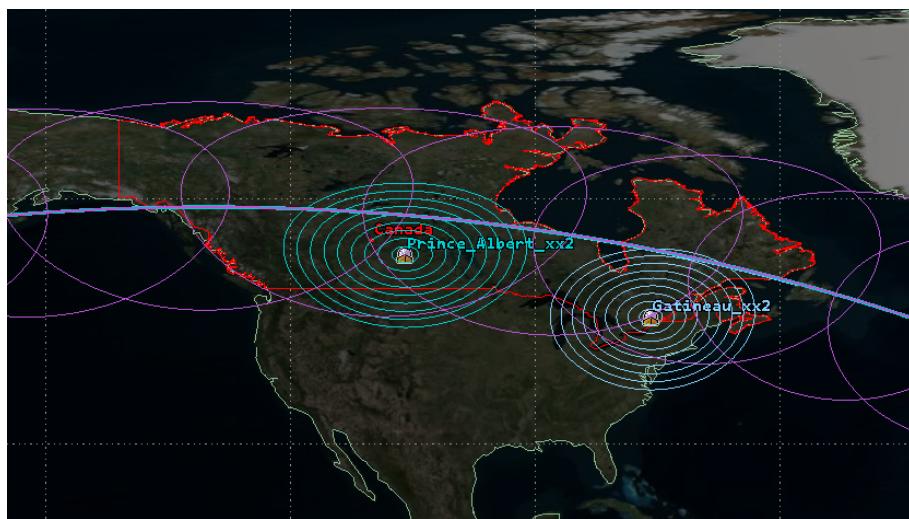

Figure 1: Ground swath of SARGE over continental Canada. Ground stations are shown in teal and sky blue, and the majority of Canada is outlined in red ($A \approx 8.342 \times 10^6 \text{ km}^2$). The magenta circles show the coverage of the SAR beam at some discrete points in time.

The orbital parameters are summarized in Table 1. We can see that the chosen orbit is a circular retrograde orbit with a period of about one sidereal day. This regularity allows the satellite to image, process, and transmit one fourteenth of Canada each day, with a consistent and regular ground station access window.

Basic Orbital Parameters			
Period P	86170.5 s	Arg. of Perigee ω	0°
Eccentricity e	0.0	LAN Ω	50°
Inclination i	121°	True Anomaly v	30°
Derived Quantities			
Orbit Radius r	42166.26 km	Orbital Altitude h	35788.12 km
Velocity v	3.074 km s ⁻¹	Orbits per Day n	1.002663 d ⁻¹

Table 1: Orbital parameters and convenient derived quantities.

At high altitudes, like GEO, the gravitational forces of the Sun and the Moon become significant, but air drag is generally negligible [2, p. 81]. As well, the high inclination of SARGE allows it to avoid most of the clutter in the GEO belt, since most of the objects are within <5° inclination [3, p. 140]. Another advantage is the lack of an eclipse time in service (there may be a short eclipse during transit to orbit), as shown in Figure 5 in Section 3.3.2. Stationkeeping requirements are also quite low, as explored in Appendix A.1 and mentioned in Section 3.3.5, since the oblateness of Earth is primarily a factor in lower inclination orbits.

3 Spacecraft Bus

3.1 Mass and Power Budget

According to David Everett of the NASA Goddard Space Flight Center, the first of the three steps of mass estimation is "A rough order of magnitude based on payload mass" [3, p. 399]. Given that sentiment, and approximate sizing of the power array (see Section 3.3.2), the initial mass estimate is based on data representative of mission type and historical data given in Table 14-18, which can be found in Appendix E, Figure 8, and summarized in Table 2, with comments noted in the third column.

Subsystem	Mass%	Mass	Comments
Payload	32 %	200 kg	Provided in requirements
Structure & Mechanisms	24 %	150 kg	Taken from Table 14-18
Thermal Control	6 %	36 kg	11 kg taken from Power subsystem
Power (incl. harness)	13 %	82 kg	Less than usual since no eclipse
TT&C	4 %	25 kg	Taken from Table 14-18
Data Processing	3 %	19 kg	"
ADCS	8 %	50 kg	13 kg taken from Power
Propulsion	7 %	44 kg	Taken from Table 14-18
Other	3 %	19 kg	"
Total Dry Mass	100 %	625 kg	
Propellant	142 %	885 kg	Double expected amount in Table 14-18
Kick motor	12 %	75 kg	Estimated mass of a jettisonable liquid motor
Wet Mass		1585 kg	

Table 2: Preliminary mass budget estimation, based on provided payload mass and the listing for "High Earth" in the SME-SMAD [3].

The breakdown of the power subsystem is available in Table ?? in Section 3.3.2. Historical basis for the amount of propellant needed was insufficient for this particular satellite, primarily because of the steep inclination and the high- ΔV maneuvers required, detailed in Section 3.3.5. The total wet mass still comes in at far less than the SpaceX Falcon 9's maximum lift-off mass of 5800 kg (Table 6), so a shared launch is still feasible (especially given the compact nature of SARGE).

Like the Mass Budget in Table 2, the preliminary power budget below in Table 3 is based on David Everett's chapter of the SME-SMAD, Table 14-20 (Appendix E, Figure 9). This time, however, a modification to the suggested weights in Table 14-20 was made to accommodate the two one-axis solar array gimbals noted in Section 3.2. The payload power proportion was thus lessened by 2%, from 35% to 33% to give a corresponding power proportion of 2% to the Structures & Mechanisms subsystem. The solar array and battery sizing calculations are presented in Section 3.3.2.

Subsystem	Power%	Avg. Power	Comments
Payload	33 %	350 W	Specified in requirements, mod. from Table 14-20
Structure & Mechanisms	2 %	21 W	Mod. from Table 14-20
Thermal	14 %	148 W	Taken from Table 14-20
Power (incl. harness)	7 %	75 W	"
TT&C	16 %	170 W	"
Data Processing	10 %	106 W	"
ADCS	16 %	170 W	"
Propulsion	2 %	21 W	"
Total	100 %	1061 W	

Table 3: Preliminary power budget estimation, based on provided payload mass and the listing for "High Earth" in the SME-SMAD [3], modified to allow for powered mechanisms.

3.2 Configuration

The configuration of SARGE is a nadir-pointing 3-axis stabilized solar-powered satellite. The two solar arrays are gimbaled in one axis with a range of $\pm 10^\circ$ to account for the slight variation in the spacecraft's orientation with respect to the sun as it travels along its orbital path (this angle was found in Appendix C.2). The size of the spacecraft can be estimated using the relations listed in Slideshow 3, Configuration, and shown in Table 4 below.

Characteristic	Equation	Estimate
Volume (m^3)	$V = 0.01M$	$15.85 m^3$
Linear Dimension (m)	$L = 0.25M^{1/3}$	2.91 m
Body Area (m^2)	$A_b = V/L$	$5.44 m^2$
Moment of Inertia (kgm^2)	$I = 0.01M^{5/3}$	$2155 kgm^2$

Table 4: Estimate of spacecraft dimensions, where M is spacecraft wet mass in kg.

(Comment on the estimations). The mark is actually for assumptions for calculations? Idk, I modelled the satellite to fit the payload bruh.

An annotated isometric view of the preliminary design/layout is shown in Figure 2.

As can hopefully be seen, the major components currently include 2 solar arrays, articulated only for launching, via single-shot hinges at each meeting point. These arrays are gimbaled in one axis, shown in the front view, Figure 3. The direction of travel is shown in Figure 2, as well as the nadir pointing direction.

Since the masses of the solar arrays are identical, and they are symmetric about the nadir axis, and since the mass proportion of the payload is only around 32% of the total dry mass, the remaining subsystems should make it so that the center of mass is not located within the payload container. This means that an ADCS system with reaction wheels should be able to be located directly in line with all three axes relative to the center of inertia, so pointing should be easily controllable. The remaining subsystems will all ideally fit in the remaining payload-sized area to the right of the payload in Figure 3.

More engineering drawings are available in Appendix G.

Drawings (3.5)

Justification (2)

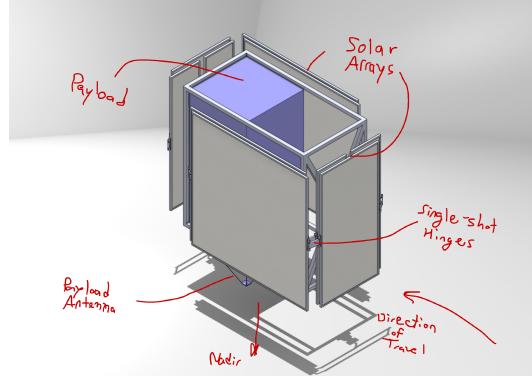

Figure 2: Isometric view of the satellite with annotation in red to aid understanding.

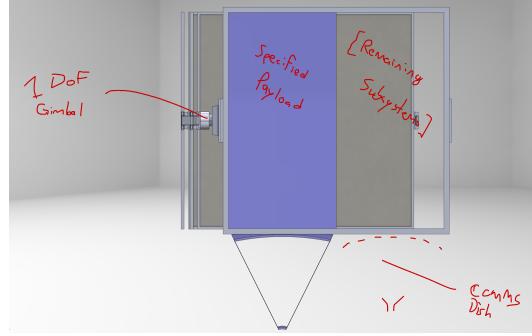

Figure 3: Front view of SARGE with annotation in red. One of the solar panel arrays is hidden so as not to obstruct the interior of the frame.

3.3 Preliminary Design of Spacecraft Subsystems

3.3.1 Communications Subsystem

Based on both slide deck 6, "TTC", and select portions of the SME-SMAD, the uplink and downlink link budgets are summarized in Table 5. As well, the downlink and uplink frequencies were chosen according to Professor Jim Wight's course handout for ELEC 4509. It's noted in that handout that frequency ranges 7.25 - 7.30 GHz and 7.975 - 8.025 GHz are reserved for downlink and uplink satellite communications, respectively [4, II, p. 3]. The downlink budget was conceived using the data rate/budget calculations in Appendix D. As a quick summary, the amount of data transmitted per 14 days is about 1 TB, with a daily access window of 9.5 h and a downlink data rate during that window of about 2.5 MBs^{-1} , for a (QPSK-encoded) bandwidth of about 12 MHz on a 7.275 GHz carrier.

Unlike the preliminary design, for this design the uplink receiving antenna (i.e. the one on the spacecraft) is no longer the same as the parabolic downlink antenna. The concern is that the parabolic antenna is too directional for the satellite to reliably establish telecommand communications while in transit to the desired orbit. To mitigate this risk, several 4λ monopole antennas are now used to telecommand uplink. While long monopole antennas are usually undesirable for ground communications (as they direct much of the signal vertically), they are a perfect application for satellite telecommand. A length of 4λ was chosen based on the far-field radiation pattern shown in Figure 4a.

To estimate the gain of a 4λ antenna for an 8 GHz uplink, a model in Ansys HFSS was used, which resulted in the 3D gain plot in Figure 4b, for a maximum gain of 6.49 dB. Why it doesn't match Figure 4a, I'm not sure, but it should still serve well as the telecommand antenna(s), since the margin is still quite high.

The uplink C/N_{achieved} was calculated using the following expression, where square brackets indicate logarithmic quantities:

$$[C/N]_{\text{achieved}} = [P_t] + [G_t] + [G_r] - [L_{\text{path}}] - [L_{\text{point}}] - [L_{\text{atmosphere}}] - [k] - [T] - [B] \quad (1)$$

Whereas the downlink C/N_{achieved} was calculated using a slightly different methodology, where the mini-

Uplink	Value	Unit	Comments
P_t	23.01	dBW	200 W ground transmitter assumed
G_t	57.74	dB	Eq. 35
L_{path}	202.68	dB	Eq. 36
L_{point}	18.42	dB	Eq. 38
$L_{\text{atmosphere}}$	10.00	dB	Assumed
k	-228.60	dBJK^{-1}	
B	37.00	dBHz	Eq. 40
G_r	6.49	dB	Figure 4b
T	14.31	dBK	Assumed
C/N_{achieved}	33.42	dB	Eq. 1
C/N_{required}	8.16	dB	Eq. 42
Margin	25.27	dB	
Downlink	Value	Unit	Comments
P_t	20.00	dBW	100 W of 170 W estimated in power budget
G_t	28.61	dB	Eq. 30
L_{path}	201.85	dB	Eq. 31
L_{point}	0.36	dB	Eq. 33
$L_{\text{atmosphere}}$	10.00	dB	Assumed
k	-228.60	dBJK^{-1}	
B	70.77	dBHz	Eq. 29
G/T	46.94	dBK^{-1}	Eq. 2
C/N_{achieved}	41.17	dB	Eq. 3
C/N_{required}	11.52	dB	Eq. 34
Margin	29.65	dB	

Table 5: Preliminary link budget, based on noted assumptions and analyses detailed in Appendix D.

imum certifiable G/T figure is found by [4, I, p. 40]:

$$\frac{G}{T} \geq 40.7 \text{ dB} + 20 \log \frac{f}{4} \quad (2)$$

where G/T is in dBK^{-1} , and f is in GHz. Since that's the minimum figure of merit to be certified for a ground station, I took that as the figure of merit for Gatineau. Then,

$$[C/N]_{\text{achieved}} = [P_t] + [G_t] + \left[\frac{G}{T} \right] - [L_{\text{path}}] - [L_{\text{point}}] - [L_{\text{atmosphere}}] - [k] - [B] \quad (3)$$

The ground station transmit power and the satellite noise temperature were both assumed based on representative data in the SME-SMAD. The G/T figure in equation 2 is specifically for Telesat certification, but that should be applicable given the age of the Gatineau station and Telesat's presence in the area. The 10 dB atmosphere loss is mostly an expression of an allowable margin for atmospheric losses. Further analysis would be required to get an accurate estimate of expected atmospheric losses. Typically, they should be pretty low, since the signal really doesn't spend much time passing through the atmosphere at all.

3.3.2 Power Subsystem

max eclipse time calculations (3)

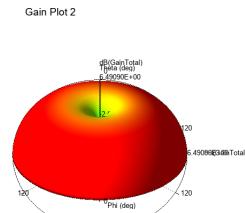

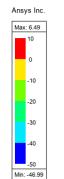

solar panel sizing and power generation calcs (3)

bus design (voltage, regulation) and explanation/justification (1)

mechanism selection and explanation/justification (2.5)

4 Launcher Selection Trade Study

A selection of launch platforms still in use as of 2025 were considered, with the key parameters summarized in Table 6. All launchers deliver their payload to GTO, with fairly minor differences in delivered transfer orbit, with the exception of the Ariane 62.

Platform	Country	i (°)	h_p (km)	h_a (km)	ω_p (°)	M (kg)	D (m)	Cost
SpaceX Falcon 9 [6]	USA	28.5	185	35788	0	5800†	3.7	69.75 [7]
Ariane 62 [8]	France	6	250	35786	178	4500	5.4	88 [9]
Atlas V 401 [10]	USA	27	185	35786	180	4750	4.0	109 [11]
Long March 3B [12]	China	28.5	200	35786	178	5100	4.0	70 [13]

Table 6: Selected launch platform comparison. †: includes payload adapter. Prices in millions USD, not adjusted for inflation.

explain shared launch reasoning, or actually evaluate if shared launch is even possible given the huge propulsion requirements

5 Schedule

worth 2 marks :/
order of various design stages, can include chart (2)

6 Cost

worth 2 marks :/
major cost elements (launcher, payload, testing, insurance) (1)
reliable sources references (textbook, other missions, etc) (1)

7 Conclusions

summarize major values/parameters (3)
discuss future work (2)

Although further analysis is required to ensure that the current configuration can reject/retain enough heat, and the delta V budget is yet to be done, the current iteration of SARGE looks to be reasonable. The mass distribution and total mass falls within the ranges typical of a GEO mission. The total estimated power draw is somewhat lower than what is mentioned in the course slides. The link budget has good margins, even after adding an assumed atmospheric loss.

A Orbital Perturbations and ΔV

SME-SMAD equations (9-46) and (9-47) on pg. 219 give approximate worse case ΔV relations per year [3]:

$$\Delta V_{\text{Moon}} = 102.67 \cos \alpha \sin \alpha \quad (\text{m/s per year}) \quad (4)$$

$$\Delta V_{\text{Sun}} = 40.17 \cos \gamma \sin \gamma \quad (\text{m/s per year}) \quad (5)$$

where α is the angle between the orbit plane and the Moon's orbit, and γ is the angle between the orbit plane and the ecliptic.

A.1 Stationkeeping

The angles estimated in Appendix C.2 and illustrated in Figure 7, substituted into the preceding expressions, yield:

$$\Delta V_{\text{Moon}} = 102.67 \cos 92.42^\circ \sin 92.42^\circ = 4.331 \text{ m/s/yr} \quad (6)$$

$$\Delta V_{\text{Sun}} = 40.17 \cos 97.56^\circ \sin 92.42^\circ = 5.239 \text{ m/s/yr} \quad (7)$$

And then, for the design lifetime of 5 years, the total ΔV for North-South stationkeeping is the product of the sum of the above:

$$\Delta V_{NS} = (\Delta V_{\text{Moon}} + \Delta V_{\text{Sun}}) \times 5 \text{ yr} = 47.85 \text{ m s}^{-1} \quad (8)$$

This is significantly less than the example value of about 51.48 m/s/yr given in the SME-SMAD for a GEO orbit with an inclination i of 0° [3]. This makes sense, since for a equatorial GEO orbit the Ecliptic and Lunar planes would be between 23.44° and 28.68° , whereas SARGE's highly inclined orbital plane is at nearly right angles to the Ecliptic and Lunar planes, somewhat balancing the perturbing forces of both.

The transverse (East-West) stationkeeping requirement is mentioned as about 10 % of the North-South stationkeeping requirements [3], however I believe that the high inclination of SARGE will work against us in this scenario, as the oblateness of Earth around the equator will have a more pronounced effect for orbits that do not closely follow the equator. As well, this oblateness likely has an effect on the North-South stationkeeping, since we're dealing with neither a polar nor equatorial orbit. For this reason, I'm going to estimate the East-West stationkeeping to be equal to the North-South:

$$\Delta V_{EW} = \Delta V_{NS} = 47.85 \text{ m s}^{-1} \quad (9)$$

This ought to roughly account for the stationkeeping requirements of the spacecraft at this stage of design.

A.2 Decommissioning

The SME-SMAD recommends handling the special scarcity and properties of the GEO orbit (specifically its vulnerability to debris and junk) by raising spacecraft 500 km above GEO at the end of their life. The ΔV required for that is

$$\Delta V_{\text{disposal}} = 18 \text{ m s}^{-1} \quad (10)$$

from SME-SMAD page 233 for decommissioning a GEO satellite [3], and the propellant mass will be found at a later date after an in-depth ΔV analysis.

A.3 Orbital Transfer

The transfer from the SpaceX GTO orbit in Table 6 will be a combined plane-change and elliptical-to-circular maneuver. The ΔV required for such a change is [14]:

$$\Delta V = \sqrt{v_1^2 + v_2^2 - 2v_1 v_2 \cos \Delta i} \quad (11)$$

where $\Delta i = 121^\circ - 28.5^\circ = 92.5^\circ$, and v_1, v_2 are the orbital velocities of the transfer orbit and final orbit respectively. The full calculation is scanned and attached in Appendix F. Hand calculations were chosen as a change of pace. The final result is a ΔV of 3.5253 km s^{-1} .

B Power and Configuration Implications

B.1 Power Collection and Storage

Given the estimated total average power presented in Table 3, 1061 W, the required solar panel coverage can be estimated following the example in slide deck 7, "Power", where the following expression is provided on slide 17:

$$PD_{\text{out}} = PD_{\text{in}} \eta \cos \theta \quad (12)$$

where $PD_{\text{out/in}}$ is the power density of out of and into the solar array in Wm^{-2} , η is the power conversion efficiency of the cells, and θ is the solar incident angle. Taking the incident solar power as 1366 Wm^{-2} , and the achieved efficiency of GaAs cells provided in slide 18 of 18.5 %, with a worst-case incident angle of about 10° (since the angle of the orbital plane to the ecliptic is 97.56° , found in Appendix C.2), then

$$PD_{\text{out}} = 1366 \text{ Wm}^{-2} \cdot 18.5\% \cdot \cos(10^\circ) = 248.87 \text{ Wm}^{-2} \quad (13)$$

Then, dividing the total average power required by the spacecraft (and noting that the spacecraft spends no time in eclipse), the minimum required illuminated area of the solar array is

$$A_{\text{solar,min}} = \frac{P_{\text{total}}}{PD_{\text{out}}} = 4.26 \text{ m}^2 \quad (14)$$

Since the spacecraft is orbiting in a plane nearly perpendicular to the ecliptic plane, a 1 DoF mechanism for the pointing of the solar array with an angular envelope of $\pm 10^\circ$ should be sufficient to ensure optimal solar collection. This fact and the lack of eclipse time is well conveyed by Figure 5 below, showing no part of the orbital track lying in eclipse.

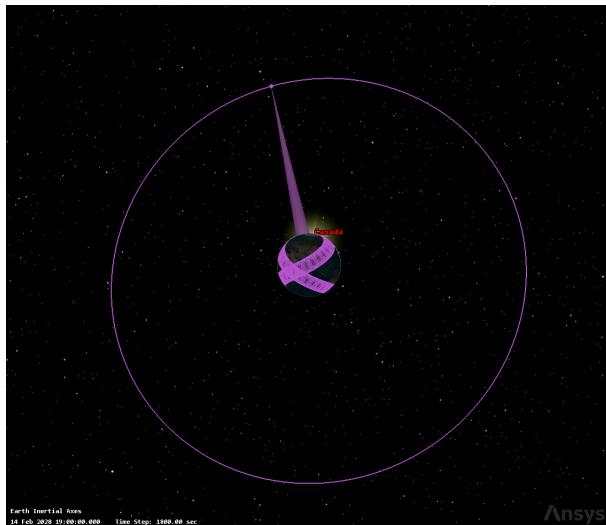

Figure 5: Demonstration of zero eclipse time via STK 3D view. The sun is visible just over the horizon.

B.2 Configuration Choices

In order to accommodate the necessary surface area of the solar panels in a compact way with margins to account for structural frames that would block cells of the solar array, and to pre-emptively take into account the packing of the spacecraft into a launch platform, a quick sketch (Figure ??) showed that the structure should follow roughly a form factor of $1 \text{ m} \times 1 \text{ m} \times 0.5 \text{ m}$. This allows the compact packing of nominally 6 m^2 of solar panels, which well exceeds the required 4.26 m^2 . In later analysis, it will be shown how much of a margin we have to block that area with support structures when EOL conditions and degradation is taken into account.

Table 21-5 in the SME-SMAD notes that travelling wave tube amplifiers (TWTA)s are about 50-60% efficient for X-band and weigh about 2.5 kg including power converter [3, p. 637]. Table 16-16 in the SME-SMAD notes that parabolic reflectors weigh between 10-30 kg [3, p. 484].

C Fun!

This section is named "Fun!" unironically – these were fun.

C.1 Fun Annulus Geometry

To approximate the arc angle subtended by the 10° elevation δ access requirement, I created a quick sketch shown in Figure 6 to wrap my head around the geometry. I then used the formula for worst-case distance d from slide deck 6 to find the corresponding half angle γ :

$$d = R_{\text{Earth}} \left(\sqrt{\left(\frac{r}{R_{\text{Earth}}} \right)^2 - \cos^2 \delta} - \sin \delta \right) \quad (15)$$

From my sketch,

$$\gamma = \sin^{-1} \left(\frac{d \sin(90^\circ + \delta)}{r} \right) \quad (16)$$

And thus the access ratio is the ratio between the access arc and the total arc (circumference):

$$\text{Access Ratio} = \frac{2\gamma r}{2\pi r} = 39.69\% \quad (17)$$

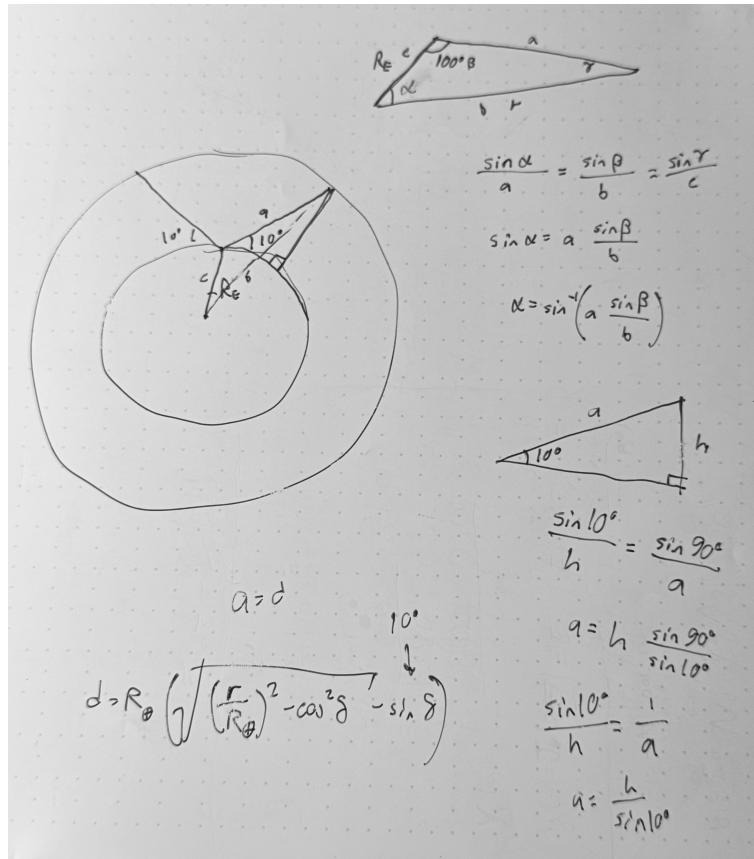

Figure 6: Figuring out the geometry to find the half-angle from the center of the Earth given the radius and elevation [Own work].

This makes a lot of sense – SARGE is far away, the elevation angle of 10° is pretty generous, and the groundtrack passes fairly close to Gatineau station (on a global scale, at least).

C.2 Fun Orbital Plane Geometry

To find α and γ for the orbital perturbation estimations in Appendix A, I estimated the angles between SARGE's orbital plane and the Sun and the Moon using the Ecliptic plane and Lunar orbit inclination values found in a figure (with no listed author) from Wikipedia.

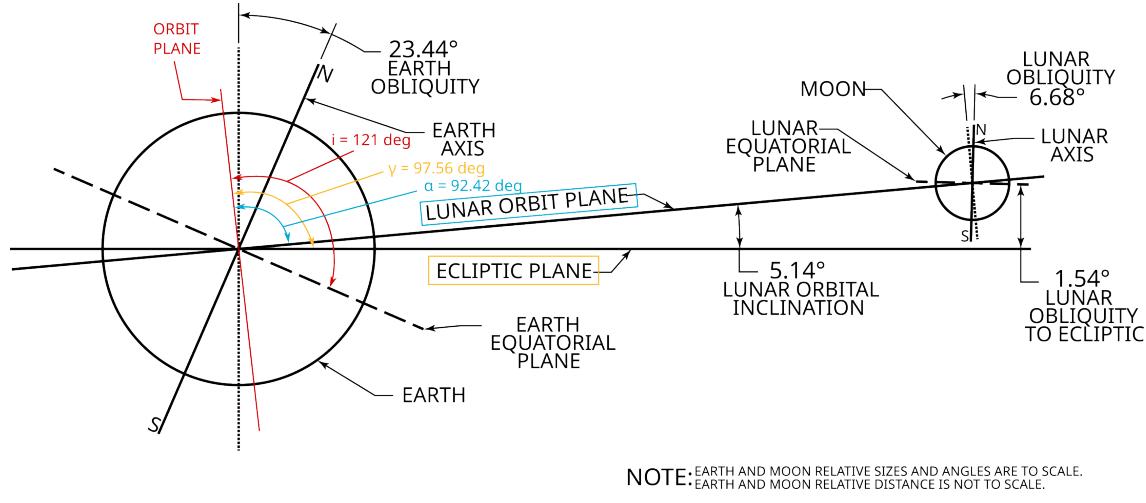

Figure 7: Angles between the orbit plane of SARGE and the Lunar orbit plane (α) and the Ecliptic plane (γ). [Author unknown, CC0, annotations (in colour) added]

From Figure 7, we can estimate that the angle between SARGE's orbit plane and the Ecliptic plane (γ) to be 97.56° , and between SARGE's orbit plane and the Lunar orbit plane (α) as 92.42° .

D Link Budget

D.1 Down

The initial step of developing the link budget is to determine how much payload data we need to download. The area of Canada proper, shown in red in Figure 1, is about $8.342 \times 10^6 \text{ km}^2$. From the mission requirements, we need to image that entire area (at least) once every 14 d. Assuming that the payload is capable of steering its beam in order to cover swaths of 100 km width, and considering an image to be $100 \text{ km} \times 100 \text{ km}$, with a linear resolution of 5 m such that each pixel is 25 m^2 and contains 16 bit of data, we estimate the amount of data required to image all of Canada using the following:

$$\text{Image Pixels} = \frac{\text{Image Area}}{(\text{Linear Resolution})^2} = 4.0 \times 10^8 \text{ pixels} \quad (18)$$

Then, the size of each image:

$$\text{Image Size} = \text{Pixel Size} \times \text{Image Pixels} = 800 \text{ MB} \quad (19)$$

Then, the images required to cover Canada, with a 4% swath overlap accommodation:

$$\text{Images per Canada} = \frac{A_{\text{Canada}}}{\text{Image Area}} \times 1.04 \approx 868 \text{ images} \quad (20)$$

And thus, the amount of data required to image Canada once:

$$\text{Canada Size} = \text{Images per Canada} \times \text{Image Size} = 694.05 \text{ GB} \quad (21)$$

Over 14 d, the average payload data rate is then:

$$R_{\text{payload,avg}} = \frac{\text{Canada Size}}{14 \text{ d}} = 573.78 \text{ kB s}^{-1} \quad (22)$$

This does not include the housekeeping data specified in the mission requirements and summarized in Table 7 below.

The total housekeeping data per image can then be found via

$$\begin{aligned}\text{Housekeeping per Image} &= \text{Image Size} \times \text{Error Detection} + \text{Latitude} + \text{Longitude} \\ &\quad + \text{Altitude} + \text{Time} + \text{Synchronization} = 300 \text{ MB/image} \quad (23)\end{aligned}$$

The total housekeeping data per Canada:

$$\text{Housekeeping Size} = \text{Housekeeping per Image} \times \text{Images per Canada} = 260.27 \text{ GB} \quad (24)$$

And the average housekeeping data rate:

$$R_{\text{housekeeping,avg}} = \frac{\text{Housekeeping Size}}{14 \text{ d}} + \text{Health Data Rate} = 215.17 \text{ kB s}^{-1} \quad (25)$$

To penultimately culminate in the *average* downlink data rate:

$$R_{\text{DL,avg}} = R_{\text{payload,avg}} + R_{\text{housekeeping,avg}} = 788.95 \text{ kB s}^{-1} \quad (26)$$

And as found in Appendix C.1, the proportion of time SARGE is within 10° elevation of Gatineau is 39.69 %, and thus the total access time is:

$$T_{\text{access}} = P \times 39.69 \% \approx 9.5 \text{ h d}^{-1} \quad (27)$$

From the guidance given in class, approximately 20 % of access window should be allocated to uplink, thus the downlink window is 80 % of T_{access} , and the actual downlink rate can be found:

$$R_{\text{DL}} = \frac{R_{\text{DL,avg}}}{\frac{80\% \times T_{\text{access}}}{P}} = 2.485 \text{ MB s}^{-1} \quad (28)$$

So the downlink rate required is about 2.485 MB s^{-1} , which transmits for about 7.6 h every sidereal day. The bandwidth for QPSK (our downlink encoding scheme) is:

$$B = 0.6R = 11.928 \text{ MHz} \quad (29)$$

Then, as noted in Section 3.2, the communications satellite on SARGE is a parabolic antenna with a diameter D_t of 0.5 m. Assuming a transmission efficiency η_t of 50 %, and noting that the wavelength λ of the downlink center frequency of 7.275 GHz is 4.12 mm, the predicted gain is

$$G_t = \eta_t \left(\frac{\pi D_t}{\lambda} \right)^2 = 726 \quad (30)$$

The path loss for the downlink direction is:

$$L_{\text{path}} = \left(\frac{4\pi d}{\lambda} \right)^2 \approx 6.53 \times 10^{-21} \quad (31)$$

Data	Quantity	Unit
Error Detection	3	bit B^{-1}
Latitude	32	bit/image
Longitude	32	bit/image
Altitude	32	bit/image
Time	64	bit/image
Synchronization	24	bit/image
Health Data Rate	26.66...	bits^{-1}

Table 7: Summary of required housekeeping data per mission requirements.

And the pointing accuracy loss can be estimated by finding the $\theta_{3\text{dB}}$ angle via the relationship in slide deck 6:

$$\theta_{3\text{dB}} \approx 70^\circ \frac{\lambda}{D} = 5.77^\circ \quad (32)$$

and then, assuming a pointing error ϵ of 1° for the spacecraft:

$$[L_{\text{point}}] = 12 \left(\frac{\epsilon}{\theta_{3\text{dB}}} \right)^2 = 0.361 \text{ dB} \quad (33)$$

And finally, to find the required carrier to noise ratio, with a minimum bit error rate BER of 10×10^{-5} for the downlink, as suggested in slide deck 6:

$$C/N_{\text{required}} = \frac{R}{B} \ln \left(\frac{1}{2BER} \right) = 14.20 \text{ dB} \quad (34)$$

Whew.

D.2 Up

The uplink analysis is much the same as the downlink analysis presented just previously, except we just assume a transmission rate of 2.5 kbits^{-1} , and we're using BFSK as recommended in slide deck 6. As well, for lack of better information and based on the ballparks present in the SME-SMAD, we assume a transmitter power at the basestation of 200 W. From Natural Resources Canada, the diameter of the Gatineau satellite dish is 13 m, and we'll assume a pointing accuracy ϵ of 0.25° and still a transmit efficiency η_t of 50 %. Then the transmitter gain is:

$$G_t = \eta_t \left(\frac{\pi D_t}{\lambda} \right)^2 = 594 \times 10^3 \quad (35)$$

And the path loss is slightly different because the uplink center frequency is 8.00 GHz with a corresponding wavelength λ of 3.75 mm:

$$L_{\text{path}} = \left(\frac{4\pi d}{\lambda} \right)^2 \approx 5.40 \times 10^{-21} \quad (36)$$

And the $\theta_{3\text{dB}}$:

$$\theta_{3\text{dB}} \approx 70^\circ \frac{\lambda}{D} = 0.20^\circ \quad (37)$$

With a pointing loss of:

$$[L_{\text{point}}] = 12 \left(\frac{\epsilon}{\theta_{3\text{dB}}} \right)^2 = 18.42 \text{ dB} \quad (38)$$

A bandwidth of (according to slide deck 6):

$$B = 2R(1 + \beta) = 5016 \text{ Hz} \quad (39)$$

$$\beta = \Delta f / f_{\text{mod}} = 0.003125 \quad (40)$$

$$\Delta f = 25 \text{ MHz} \quad (\text{Half of max channel BW}) \quad (41)$$

And finally, the minimum carrier to noise is calculated in the same was as Eq. 34, but with a BER of 10×10^{-7} for telecommand, also as mentioned in slide deck 6:

$$C/N_{\text{required}} = \frac{R}{B} \ln \left(\frac{1}{2BER} \right) = 8.16 \text{ dB} \quad (42)$$
